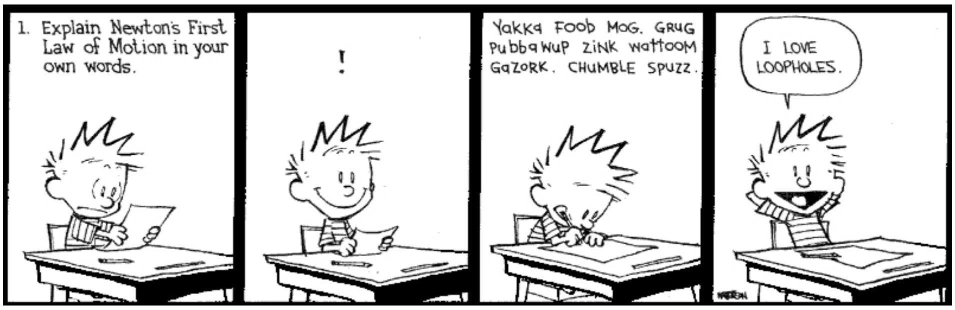
Something very abstract and clever should go here.



I. INTRODUCTION

We will in this project study the Variational Monte Carlo (VMC) method, and use it to evaluate the ground state energy of a trapped, hard sphere Bose gas.

II. THEORY

To model the trapped bosonic gas particles we use the potential

$$V_{\text{ext}}(\mathbf{r}) = \begin{cases} \frac{1}{2}m\omega^2 r^2 & \text{(S)}, \\ \frac{1}{2}m\big[\omega^2(x^2+y^2)+\omega_z^2 z^2\big] & \text{(E)}, \end{cases} \tag{1}$$

where we can choose between a spherical (S) or an elliptical (E) harmonic trap. The two-body Hamiltonian of the system is given by

$$H = \sum_{i=1}^{N} h(\mathbf{r}_i) + \sum_{i<j}^{N} w(\mathbf{r}_i, \mathbf{r}_j), \tag{2}$$

where the single particle one body operator, h, is given by

$$h(\mathbf{r}_i) = -\frac{\hbar^2}{2m}\nabla_i^2 + V_{\text{ext}}(\mathbf{r}_i), \tag{3}$$

(we assume equal mass) and the two-body interaction operator, w, is

$$w(\mathbf{r}_i, \mathbf{r}_j) = \begin{cases} \infty & |\mathbf{r}_i - \mathbf{r}_j| \leq a, \\ 0 & |\mathbf{r}_i - \mathbf{r}_j| > a, \end{cases} \tag{4}$$

where a is the hard sphere of the particle. The trial wavefunction, $|\Psi_T\rangle$, we will be looking at is given by

$$\Psi_T(\mathbf{r}) = \Phi_T(\mathbf{r}) \prod_{j<k}^{N} f(a, \mathbf{r}_j, \mathbf{r}_k) \tag{5}$$

$$= \left(\prod_{i=1}^{N} g(\alpha, \beta, \mathbf{r}_i)\right) \prod_{j<k}^{N} f(a, \mathbf{r}_j, \mathbf{r}_k), \tag{6}$$

where α and β are variational parameters and

$$\mathbf{r} = (\mathbf{r}_1, \mathbf{r}_2, \ldots, \mathbf{r}_N, \alpha, \beta). \tag{7}$$

Here g are the single particle wavefunctions given by

$$g(\alpha, \beta, \mathbf{r}_i) = \exp\big[-\alpha(x_i^2 + y_i^2 + \beta z_i^2)\big] \equiv \phi(\mathbf{r}_i), \tag{8}$$

and $|\Phi_T\rangle$ the *Slater permanent* consisting of the N first single particle wavefunctions, and the correlation wavefunction, f, given by

$$f(a, \mathbf{r}_j, \mathbf{r}_k) = \begin{cases} 0 & |\mathbf{r}_j - \mathbf{r}_k| \leq a, \\ \left(1 - \frac{a}{|\mathbf{r}_j - \mathbf{r}_k|}\right) & |\mathbf{r}_j - \mathbf{r}_k| > a. \end{cases} \tag{9}$$

We will for brevity use the notation $\phi(\mathbf{r}_i) = \phi_i$ and $r_{jk} = |\mathbf{r}_j - \mathbf{r}_k|$.

A. Local energy

As the many-body wavefunction creates a very large configuration space, where much of the wavefunction is small, we use the Metropolis algorithm in order to move towards regions in configuration space with "sensible" values. We define the *local energy*, $E_L\mathbf{r}$, by

$$E_L(\mathbf{r}) = \frac{H\Psi_T(\mathbf{r})}{\Psi_T(\mathbf{r})}. \tag{10}$$

If $|\Psi_T\rangle$ is an exact eigenfunction of the Hamiltonian, E_L will be constant. The closer $|\Psi_T\rangle$ is to the exact wave function, the less variation in E_L as a function of $\mathbf{r}$ we get. One of the most computationally intensive parts of the VMC algorithm will be to compute E_L. We therefore find an analytical expression for E_L in terms of the trial wavefunction.

B. The drift force

A disadvantage in the use of the brute-force Metropolis algorithm is that we might be spending much computational resources in an uninteresting part of configuration space. To make smarter moves we will use the Metropolis-Hastings algorithm (which will be discussed in due time). This algorithm is dependent on the drift force of the system.

$$\mathbf{F}(\mathbf{r}) = \sum_{k=1}^{N} \mathbf{F}_k(\mathbf{r}) = \sum_{k=1}^{N} \frac{2\nabla_k \Psi_T(\mathbf{r})}{\Psi_T(\mathbf{r})}. \tag{11}$$

Using this expression we are able to move towards parts of configuration space where the gradient increases or decreases yielding a better choice of movements. We will mainly be interested in the drift force of a single particle k.

III. NON-INTERACTING HARMONIC OSCILLATORS

We start by looking at a simple system of non-interacting harmonic oscillators. That is, where $a = 0$ and $\beta = 1$. We thus get the trial wavefunction

$$\Psi_T(\mathbf{r}) = \Phi_T(\mathbf{r}) = \prod_{i=1}^{N} \exp\left[-\alpha |\mathbf{r}_i|^2\right], \tag{12}$$

where $|\mathbf{r}_i| = r_i$. As $a = 0$ the interaction term, $w(\mathbf{r}_i, \mathbf{r}_j)$, vanishes and the Hamiltonian is given by (in the spherical case)

$$H = \sum_{i=1}^{N} h(\mathbf{r}_i) = \sum_{i=1}^{N} \left(-\frac{\hbar^2}{2m} \nabla_i^2 + \frac{1}{2} m\omega^2 r_i^2 \right). \tag{13}$$

To find the drift force and the local energy we have to compute the gradient and the Laplacian of the trial wavefunction. The gradient is given by

$$\nabla_k \Psi_T(\mathbf{r}) = -2\alpha \mathbf{r}_k \Psi_T(\mathbf{r}), \tag{14}$$

whereas the Laplacian yields

$$\nabla_k^2 \Psi_T(\mathbf{r}) = \left(-2d\alpha + 4\alpha^2 r_k^2 \right) \Psi_T(\mathbf{r}), \tag{15}$$

where d is the dimensionality of the problem determined by $\mathbf{r}_k \in \mathbb{R}^d$. We can thus use the gradient to find an expression for the drift force for particle k.

$$\mathbf{F}_k(\mathbf{r}) = -2\alpha \mathbf{r}_k. \tag{16}$$

Using the Laplcian we can compute the kinteic term in the expression for the local energy. We get

$$E_L(\mathbf{r}) = \sum_{i=1}^{N} \left(-\frac{\hbar^2}{2m} \left[-2d\alpha + 4\alpha^2 r_i^2\right] + \frac{1}{2} m\omega^2 r_i^2 \right). \tag{17}$$

In natural units, with $\hbar = c = m = 1$, this reduces to

$$E_L(\mathbf{r}) = \alpha d N + \left(\frac{1}{2}\omega^2 - 2\alpha^2 \right) \sum_{i=1}^{N} r_i^2. \tag{18}$$

It is worth noting that for $\alpha = \pm\frac{1}{2}\omega$ we will find a stable value which turns out to be the exact energy minimum. This happens as the entire sum over all the random walkers disappears.

IV. INTERACTING HARD SPHERE BOSONS

Moving to the full system allowing β to vary and setting $a \neq 0$ we can write the trial wavefunction as

$$\Psi_T(\mathbf{r}) = \Phi_T(\mathbf{r}) J(\mathbf{r}), \tag{19}$$

where $|\Phi_T\rangle$ is the same Slater permanent as in Equation 6 and $J(\mathbf{r})$ is the *Jastrow factor* given by

$$J(\mathbf{r}) = \exp\left(\sum_{j<l}^{N} u(r_{jl}) \right), \tag{20}$$

where $r_{jk} = |\mathbf{r}_j - \mathbf{r}_k|$ and

$$u(r_{jk}) = \ln\left[f(a, \mathbf{r}_j, \mathbf{r}_k)\right]. \tag{21}$$

To further shorten the notation we will use $u_{jk} = u(r_{jk})$. Computing the gradient of the wavefunction we get

$$\nabla_k \Psi_T(\mathbf{r}) = \left[\nabla_k \Phi_T(\mathbf{r})\right] J(\mathbf{r}) + \Phi_T(\mathbf{r}) \nabla_k J(\mathbf{r}). \tag{22}$$

The gradient of the Slater permament for particle k is given by

$$\nabla_k \Phi_T(\mathbf{r}) = \nabla_k \phi_k \prod_{i\neq k}^{N} \phi_i = \frac{\nabla_k \phi_k}{\phi_k} \Phi_T(\mathbf{r}). \tag{23}$$

The gradient of the Jastrow factor is given by

$$\begin{aligned}
\nabla_k J(\mathbf{r}) &= J(\mathbf{r}) \nabla_k \sum_{m<n}^{N} u_{mn} && (24) \\
&= J(\mathbf{r}) \left(\sum_{m=1}^{k-1} \nabla_k u_{mk} \sum_{n=k+1}^{N} \nabla_k u_{kn} \right) && (25) \\
&= J(\mathbf{r}) \sum_{m\neq k}^{N} \nabla_k u_{km}, && (26)
\end{aligned}$$

where the gradient of the interaction term splits the antisymmetric sum into two parts. As $r_{ij} = r_{ji}$ we can combine these sums into a single sum. This in total yields the gradient

$$\nabla_k \Psi_T(\mathbf{r}) = \left(\frac{\nabla_k \phi_k}{\phi_k} + \sum_{m\neq k}^{N} \nabla_k u_{km} \right) \Psi_T(\mathbf{r}). \tag{27}$$

The Laplcian of the trial wavefunction is found by finding the divergence of Equation 27.

$$\nabla_k^2 \Psi_T(\mathbf{r}) = \left(\nabla_k \left[\frac{\nabla_k \phi_k}{\phi_k} \right] + \sum_{m\neq k}^{N} \nabla_k^2 u_{km} \right) \Psi_T(\mathbf{r}) \tag{28}$$

$$+ \left(\frac{\nabla_k \phi_k}{\phi_k} + \sum_{m\neq k}^{N} \nabla_k u_{km} \right)^2 \Psi_T(\mathbf{r}), \tag{29}$$

where the squared term came from taking the gradient of the trial wavefunction. To further simplify we divide by the trial wavefunction. This yields

$$\frac{\nabla_k^2 \Psi_T(\mathbf{r})}{\Psi_T(\mathbf{r})} = \frac{\nabla_k^2 \phi_k}{\phi_k} + 2 \frac{\nabla_k \phi_k}{\phi_k} \sum_{m\neq k} \nabla_k u_{km} + \sum_{m\neq k}^{N} \nabla_k^2 u_{km} + \left(\sum_{m\neq k}^{N} \nabla_k u_{km} \right)^2. \tag{30}$$

To go from here we have to find the gradient and the Laplacian of the single particle functions, ϕ_k, and the interaction functions u_{km}. For the single particle functions we use Cartesian coordinates when finding the derivatives whereas we for the interaction functions will use spherical coordinates and do a variable substitution. Beginning with the gradient of the single particle functions we get

$$\nabla_k \phi_k = \nabla_k \exp\left[-\alpha(x_k^2 + y_k^2 + \beta z_k^2) \right] \tag{31}$$

$$= -2\alpha(x_k \mathbf{e}_i + y_k \mathbf{e}_j + \beta z_k \mathbf{e}_k)\phi_k. \tag{32}$$

Note that the subscripts on the unit vectors $\mathbf{e}_i$ are *not* the same as the subscripts used for its components. The Laplacian yields

$$\nabla_k^2 \phi_k = \left[-2\alpha\big(d - 1 + \beta\big) + 4\alpha^2 \big(x_k^2 + y_k^2 + \beta^2 z_k^2\big) \right] \phi_k, \tag{33}$$

with d as the dimensionality of the problem. In order to derive the interaction functions we have to do a variable substitution using $r_{km} = |\mathbf{r}_k - \mathbf{r}_m|$. We can then rewrite the ∇_k-operator as

$$\nabla_k = \nabla_k \frac{\partial r_{km}}{\partial r_{km}} = \nabla_k r_{km} \frac{\partial}{\partial r_{km}} \tag{34}$$

$$= \frac{\mathbf{r}_k - \mathbf{r}_m}{r_{km}} \frac{\partial}{\partial r_{km}}. \tag{35}$$

Applying this version of the ∇_k-operator to u_{km} yields

$$\nabla_k u_{km} = \frac{\mathbf{r}_k - \mathbf{r}_m}{r_{km}} \frac{\partial u_{km}}{\partial r_{km}}. \tag{36}$$

For the Laplacian we switch a little back and forth between the two ways of representing the ∇_k-operator. We thus get

$$\nabla_k^2 u_{km} = \frac{\nabla_k \mathbf{r}_k}{r_{km}} \frac{\partial u_{km}}{\partial r_{km}} + \left[\nabla_k \frac{1}{r_{km}} \right] (\mathbf{r}_k - \mathbf{r}_m) \frac{\partial u_{km}}{\partial r_{km}} + \frac{\mathbf{r}_k - \mathbf{r}_m}{r_{km}} \nabla_k \frac{\partial u_{km}}{\partial r_{km}} \tag{37}$$

$$= \frac{d}{r_{km}} \frac{\partial u_{km}}{\partial r_{km}} - \frac{(\mathbf{r}_k - \mathbf{r}_m)^2}{r_{km}^3} \frac{\partial u_{km}}{\partial r_{km}} + \frac{(\mathbf{r}_k - \mathbf{r}_m)^2}{r_{km}^2} \frac{\partial^2 u_{km}}{\partial r_{km}^2} \tag{38}$$

$$= \frac{d-1}{r_{km}} \frac{\partial u_{km}}{\partial r_{km}} + \frac{\partial^2 u_{km}}{\partial r_{km}^2}, \tag{39}$$

where d is again the dimensionality of the problem. In total we can state an intermediate version of the Laplacian occuring in the local energy as

$$\frac{\nabla_k^2 \Psi_T(\mathbf{r})}{\Psi_T(\mathbf{r})} = \frac{\nabla_k^2 \phi_k}{\phi_k} + 2 \frac{\nabla_k \phi_k}{\phi_k} \sum_{m\neq k}^{N} \frac{\mathbf{r}_k - \mathbf{r}_m}{r_{km}} \frac{\partial u_{km}}{\partial r_{km}} + \sum_{m\neq k}^{N} \left(\frac{d-1}{r_{km}} \frac{\partial u_{km}}{\partial r_{km}} + \frac{\partial^2 u_{km}}{\partial r_{km}^2} \right) + \sum_{m,n\neq k}^{N} \frac{\mathbf{r}_k - \mathbf{r}_m}{r_{km}} \frac{\mathbf{r}_k - \mathbf{r}_n}{r_{kn}} \frac{\partial u_{km}}{\partial r_{km}} \frac{\partial u_{kn}}{\partial r_{kn}}. \tag{40}$$

Moving on to the derivatives of the interaction terms, u_{km}, to get an explicit expression for the Laplacian.

$$\frac{\partial u_{km}}{\partial r_{km}} = \frac{a}{r_{km}(r_{km} - a)}, \tag{41}$$

$$\frac{\partial^2 u_{km}}{\partial r_{km}^2} = \frac{a^2 - 2a r_{km}}{r_{km}^2 (r_{km} - a)^2}. \tag{42}$$

V. ALGORITHMS

In the project we rely on a Monte Carlo approach of random sampling to obtain numerical results. Ironic, is it not? To rely randomness to solve problems that must be naturally deterministic? We simulate random walks over a volume in order to find optimal parameters in our trial wavefunctions. The most common of such methods, which we make use of herein, is the Metropolis-Hastings algorithm.

A. Metropolis-Hastings Algorithm

The Metropolis-Hastings algorithm can in our particular situation be condensed down to the following steps,

1. The system is initialised by a certain number N of randomly generated positions, or particles. This allows us to evaluate the wavefunction at these points and compute the local energy E_L.

2. The initial configuration is changed by setting a new position for one of these particles. The particle is picked at random.

3. A ratio between new wavefunction density and the previous (initial) density is computed and compared to a random number. This acceptance probability decides if the particle move is rejected or accepted. The particle is only allowed to move a predetermined step length.

4. If the particle movement is accepted and the local energy E_L is computed for the new system.

5. Repeat steps until convergence and an optimum is reached.

The algorithm described above can be applied in an "exhaustive" search of the parameter space in order to find the optimal parameters. Whether a proposed move is accepted or not is determined by a transition probability and the acceptance probability. The strength of the algorithm is that the transition algorithm need not be known.

1. Importance Sampling

A problem with the naïve Metropolis-Hastings sampling approach is that the sampling of the position space is done with no regard for where we are likely to find a particle. This problem can be remedied through a *importance sampling.* It is reasonable to assume that the particles we erratically scatter in space are prone to movement towards the peaks of the probability density as dictated by the wave function. Consider therefore the Fokker-Planck equation,

$$\frac{\partial\psi}{\partial t} = D\frac{\partial}{\partial x}\left(\frac{\partial}{\partial x} - F\right)\psi, \tag{43}$$

which described the evolution in time of a probability density function, here exchanged for the wavefunction ψ. Originaly an equation that models diffusion, we have a diffusion term D and a drift force,

$$F = \frac{2}{\psi}\frac{\partial\psi}{\partial x}. \tag{44}$$

The one-particle model corresponding to the Fokker-Planck equation is the Langevin equation,

$$\frac{\partial x}{\partial t} = DF(x) + \eta, \tag{45}$$

where η is a uniformly distributed stochastic variable. Solving Langevin's equation by Eurler's method gives a recursive relation for the subsequent new positions of a particle,

$$x_{t+\Delta t} = x_t + DF(x)\Delta t + \xi\sqrt{\Delta t}, \tag{46}$$

given a time step Δt[1] and a normally distributed stochastic variable ξ.

Now we need to change the acceptance probability of the metropolis algorithm to something that takes the new sampling method into account,

$$q(x_{\text{new}}, x) = \frac{G(x, x_{\text{new}}, \Delta t)\left|\psi_T(x_{\text{new}})\right|}{G(x_{\text{new}}, x, \Delta t)\left|\psi_T(x)\right|} \tag{47}$$

where G is the Green's function to the Fokker-Planck equation,

$$G(x_{\text{new}}, x, \Delta x) = \frac{1}{(4\pi D\Delta t)^{3N/2}}\exp\left(-\frac{(x_{\text{new}} - x - D\Delta t F(x))^2}{4D\Delta t}\right). \tag{48}$$

[1] Bear in mind that Equation 45 is only valid as $\Delta t \to 0$, a property stemming from the use of Euler's method.
